Introduction

- Motivation

- Special considerations

Description of Approach

- Underlying model

- Use of -xtgee-

Examples

- Example 1: Time-averaged difference

- Example 2: Difference in rate of change

Possible Extensions

Make sample size calculations more accessible

- ▶ Permit researchers to experiment easily with many different scenarios
- ▶ Emphasize relationship between sample size calculation and actual analysis of the data

Longitudinal studies involve special considerations

- ▶ Correlation between data points for a given individual
- ▶ Sample attrition (drop-out)
- ▶ Effect(s) of interest often have complicated form (e.g., nonlinear across time)
- ▶ Effects of other covariates

Statistical model

Let $Y_i = (y_{i1}, \dots, y_{in_i})^T$ be an $n_i \times 1$ vector of outcome values for the i th subject ($i = 1, \dots, m$), and $X_i = (x_{i1}, \dots, x_{in_i})^T$ be a corresponding $n_i \times p$ matrix of covariate values.

$$Y_i = X_i\beta + \epsilon_i$$
$$\epsilon_i \sim (0, V)$$

Note:

- ▶ Within-subject correlation $R = V/\sigma^2$
- ▶ ϵ_i and ϵ_j are independent for all $i \neq j$

Generalized least squares estimator

$$\hat{\beta}_{GLS} = \left(\sum_{i=1}^m X_i' V_i^{-1} X_i \right)^{-1} \left(\sum_{i=1}^m X_i' V_i^{-1} Y_i \right)$$

$$\begin{aligned} \text{Var}(\hat{\beta}_{GLS}) &= \left(\sum_{i=1}^m X_i' V_i^{-1} X_i \right)^{-1} \\ &= f(X, R, \sigma^2) \end{aligned}$$

Steps in using -xtgee- to calculate variance

1. Create a *pseudo-dataset* containing X and Y for m subjects
2. Enter the correlation matrix R
3. Use -xtgee- command with fixed correlation R and dispersion parameter σ^2

Example 1: Time-averaged difference

Time-averaged difference between two groups

Suppose:

- ▶ 2 groups of equal size ($m/2$ subjects each)
- ▶ All subjects measured at $n = 3$ time points (no drop-out)
- ▶ Constant within-subject correlation $\rho = 0.5$
- ▶ $\sigma^2 = 1$
- ▶ We want 90% power to detect a difference d of 0.25 at the two-sided 0.05 level.

$$\begin{aligned} m &= (4\sigma^2/nd^2)(1 + (n - 1)\rho)(z_{\alpha/2} + z_{\beta})^2 \\ &= 448 \text{ (224 per group)} \end{aligned}$$

Example 1: Time-averaged difference

Create pseudo-dataset and enter correlation matrix

```
. input g t

      g      t
1. 0 1
2. 0 2
3. 0 3
4. 1 1
5. 1 2
6. 1 3
7. end

. expand 224
(1338 observations created)

. bys t (g): gen id = _n

. gen y = uniform()

. mat R = J(3,3,0.5) + I(3)*(1-0.5)

. mat list R

symmetric R[3,3]
      c1  c2  c3
r1   1
r2   .5  1
r3   .5  .5  1
```

Example 1: Time-averaged difference

Use `-xtgee-` to calculate variance

```
. xtgee y g, i(id) t(t) corr(fixed R) scale(1)
```

```
Iteration 1: tolerance = 2.308e-16
```

```
GEE population-averaged model
Group and time vars:          id t
Link:                          identity
Family:                         Gaussian
Correlation:                   fixed (specified)

Number of obs      =      1344
Number of groups   =      448
Obs per group: min =         3
                  avg =       3.0
                  max =         3
Wald chi2(1)       =         0.01
Prob > chi2        =      0.9266

Scale parameter:          1
```

```
-----+-----
      y |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-----+-----
      g |  -0.0071089   .0771517    -0.09   0.927   -0.1583235   0.1441056
   _cons |   .5041997   .0545545     9.24   0.000    0.3972749   0.6111245
-----+-----
```

Example 1: Time-averaged difference

Use `-samps` to calculate power

```
. samps 0 0.25, alpha(0.05) n1(1) sd1(0.0771517) onesample
```

Estimated power for one-sample comparison of mean
to hypothesized value

Test H_0 : $m = 0$, where m is the mean in the population

Assumptions:

```
alpha = 0.0500 (two-sided)
alternative m = .25
sd = .077152
sample size n = 1
```

Estimated power:

```
power = 0.8998
```

Example 2: Difference in rate of change

Difference in rate of change between two groups

- ▶ 10% drop-out per time point
- ▶ Constant within-subject correlation $\rho = 0.8$
- ▶ Linear change in each group over time
- ▶ We want to compute power for detecting a 0.25 difference in the rate of change over entire study.

Example 2: Difference in rate of change

Create pseudo-dataset and enter correlation matrix

```
. xtides, i(id) t(t)
```

```
id: 1, 2, ..., 448          n =          448
t:  1, 2, ..., 3           T =           3
Delta(t) = 1; (3-1)+1 = 3
(id*t uniquely identifies each observation)
```

```
Distribution of T_i:  min      5%      25%      50%      75%      95%      max
                   1         1         3         3         3         3         3
```

Freq.	Percent	Cum.	Pattern
364	81.25	81.25	111
44	9.82	91.07	1..
40	8.93	100.00	11.
448	100.00		XXX

```
. mat R = J(3,3,0.8) + I(3)*(1-0.8)
```

Example 2: Difference in rate of change

Use `-xtgee-` to calculate variance

```
. xi: xtgee y i.g*t, i(id) t(t) corr(fixed R) scale(1)
i.g          _Ig_0-1          (naturally coded; _Ig_0 omitted)
i.g*t       _IgXt_#          (coded as above)
```

Iteration 1: tolerance = .00579064

Iteration 2: tolerance = 4.388e-16

```
GEE population-averaged model          Number of obs      =      1216
Group and time vars:                    id t              Number of groups   =      448
Link:                                    identity           Obs per group: min =        1
Family:                                  Gaussian            avg                =      2.7
Correlation:                             fixed (specified)  max                =        3
                                           Wald chi2(3)       =      0.18
Scale parameter:                         1                  Prob > chi2        =      0.9808
```

```
-----+-----
      y |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-----+-----
    _Ig_1 |  -.0121577   .1075186    -0.11  0.910   - .2228903   .1985749
      t |   .007212   .0229825     0.31  0.754   - .0378328   .0522568
  _IgXt_1 |  -.002222   .0325021    -0.07  0.945   - .065925   .061481
   _cons |   .5004684   .0760271     6.58  0.000   .351458   .6494789
-----+-----
```

Example 2: Difference in rate of change

Use `-samps` to calculate power

```
. loc d = 0.25/3
```

```
. samps 0 'd', alpha(0.05) n1(1) sd1(0.0325021) onesample
```

Estimated power for one-sample comparison of mean
to hypothesized value

Test Ho: $m = 0$, where m is the mean in the population

Assumptions:

```
alpha = 0.0500 (two-sided)
alternative m = .083333
sd = .032502
sample size n = 1
```

Estimated power:

```
power = 0.7271
```

Extensions of the basic method

- ▶ Generalized linear models

$$\text{Var}(\hat{\beta}) = f(X, \beta, R, \phi)$$

- ▶ Effects of other covariates

Note: For random X , may need to increase size of pseudo-dataset and then scale up variance estimate accordingly.
